

Three adult dogs with large fatty tumors on FNA.

Adult dog with a simple lipoma. Transverse CT image shows a well delineated, homogeneous fat density mass (asterisk) in the thoracic wall.

Adult dog with an infiltrative lipoma. Transverse CT image (level thoracic vertebra) shows a mass located between the trachea, the vertebral column, the triceps brachialis muscle and the ventral skin. The mass is partly homogeneous with a fat density (asterisk) and partly inhomogeneous (fat/soft tissue density). The mass is locally aggressive and infiltrates the surrounding muscle (arrows).

An adult dog with a liposarcoma. Transverse CT image shows an inhomogeneous mass (asterisk) at the location of juxtavertebral muscles.
